Global FX Strategy

FX Carry: Outright Yield Levels

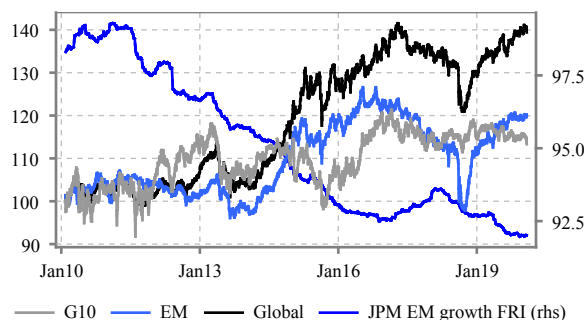

Table 1: Current holdings*

G10 Currencies	Long vs Short	Carry, %	Carry-to-risk
	USD vs CHF	2.5	0.56
	CAD vs EUR	2.3	0.63
EM Currencies			
	TRY vs ILS	9.7	1.25
	MXN vs HUF	6.7	0.73
	ZAR vs TWD	6.1	0.48
Global Currencies			
	TRY vs TWD	9.5	1.05
	ZAR vs CHF	7.4	0.66
	MXN vs JPY	7.3	1.07
	INR vs EUR	6.3	1.10
	RUB vs SEK	6.1	0.52

Table 2: Current rankings (based on previous day close)

G10 Currencies	Lowest	Carry (%)	Highest	Carry (%)
	CHF	-0.68	CAD	1.90
	EUR	-0.38	USD	1.82
EM Currencies				
	ILS	0.37	TRY	10.09
	HUF	0.5	MXN	7.21
Global Currencies				
	CHF	-0.68	TRY	10.09
	EUR	-0.38	MXN	7.21

Performance of G-10, EM and global carry baskets. Indexed to T-10Y = 100

Current 1-mo implied yield ranking; %

Net yield on global and EM carry portfolios; %

Net yield on G10 carry portfolio; %

Long-term valuations: REER-PPI deviation of net portfolio from 15y avg (%)

EM-G10 yield on carry portfolios; %

Long-term valuations: REER-PPI deviation of longs only from 15y avg (%)

* Strategy involves buying (selling) the currencies with the highest (lowest) 1-month implied yield calculated from FX forwards vs. USD in equally weighted amounts. A position can be taken on USD if it qualifies in the top (lowest) ranking. 1m US swap rate used for USD yield. Rebalances at the end of every month. All exhibits except table 2 relate to end of month portfolio.

Value vs. economic momentum(zscore)

RA carry vs. economic momentum

Valuations and implied yield of recommended global portfolio**

Suggested portfolio:

BUY	SELL
GBP	INR
TWD	THB
KRW	NOK
BRL	CLP
ILS	USD

Regional EASIs

* Strategy involves buying (selling) the five currencies with the best (worst) economic momentum ranked on the 1y zscore of 12-wk (60 bd) change in JPM growth FRI(forecast revision index) subject to 1.0 sigma threshold (USD is used if currencies don't meet this criteria). Risk is allocated to five pairs in the global basket, two in G10 and three in EM. We allow two business days for implementation of strategy

** Valuations defines as average mispricing (%deviation of REER from 15Y average) of recommended longs minus shorts in global basket. Carry defined as average implied yield of recommended longs minus shorts in global basket.

Global FX Strategy

Mean reversion based on IMM

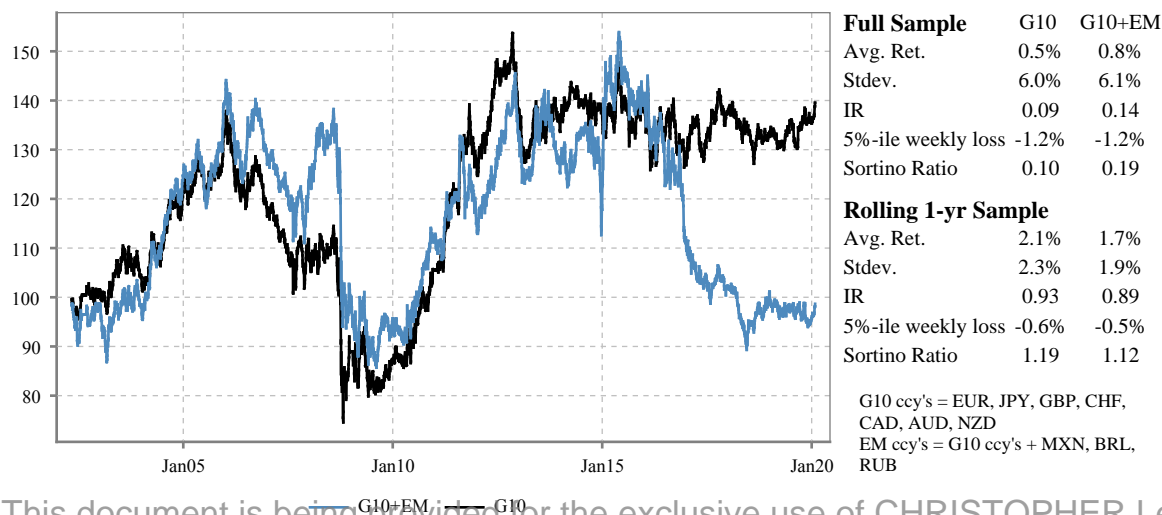

Table below shows backtest results for a simple contrarian rule. A long/short position in the currency is initiated if the IMM position exceeds a pre-determined threshold level (one and two standard deviations) around a 12-month trend. For example if non-commercial net longs on euro versus the dollar is greater than one standard deviation of the 12-month moving average of non-commercial net EUR longs then sell EUR/USD currency pair. The tables show backtest results for a 1-month holding period using weekly 1-yr z-score signals

Pair-by-pair returns from a contrarian IMM based trading rule

Cumulative returns from a contrarian IMM-based trading rule

Trading rule buys the most oversold currency and sells the most overbought currency every week based on 1-yr Z-score of IMM positions, subject to the condition that the absolute value of z-score is >=1. If oversold / overbought conditions do not meet the 1-sigma threshold, the strategy has no open positions that week

Current 1-yr Z-scores of IMM positions

Summary: pair-wise returns from trading rule*

	Avg P/L per trade	Avg Hit Rate
Average: USD pairs	0.17 %	64.3 %
Average: Non-USD crosses	0.24 %	65.4 %
Average: All crosses	0.22 %	65.1 %

Summary: Diversified basket approach +

1Y	Avg returns (% annualized)	IR
USD pairs	3.7	1.22
non-USD pairs	7.2	3.23
All pairs	3.7	1.42
5Y	Avg returns (% annualized)	IR
USD pairs	3.1	0.36
non-USD pairs	4.6	0.83
All pairs	3.2	0.50

*This pair-wise strategy is based on using the 1-year z-score of the residual from JPM 1-year short-term fair value models as a mean reversion signal. The pair is bought (sold) if the signal < -1.75 (>+1.75) and then held till the z-score reverts back to -1.0 (+1.0). Statistics shown are total holding period returns based on 5-year rolling history.

+The basket strategy allocates risk to the 3 pairs that are most mispriced (basis: absolute value of 1-year z-scores) with a diversification overlay which limits exposure of each currency (but USD) to one unit. ** Cross-sectional average of absolute value of z-score mispricing across pairs on J.P. Morgan's short-term fair value models. A higher number suggests larger FX dislocations relative to rate markets. *** Average holding period is in business days

Explanatory notes on J.P Morgan Daily FX Strategy Analytics

This daily chart packet details signals for four FX tactical trading models: (1) carry for G-10, emerging markets and global currency baskets; (2) interest-rate momentum applied to currencies; and (3) interest-rate momentum as an overlay to standard G-10 carry described in model 1; and (4) interest-rate momentum as an overlay to standard price momentum.

All models tracked in these reports are discussed in three previous J.P. Morgan research notes available on jpmorganmarkets.com/GlobalFXStrategy in the Quantitative Research Notes section: JPMorgan's FX Barometer (Normand, September 22, 2004); Rotating Between G-10 and Emerging Markets Carry (Normand, Jul 9, 2007) and Alternatives to standard carry and momentum in FX (Normand, Aug 8, 2008).

1. Global FX carry

- The global FX carry report provides pair selection and performance statistics on baskets of G-10 and emerging markets currencies.
- Each basket comprises the four currency pairs offering the highest carry-to-risk. Carry-to-risk, or volatility-adjusted carry, is calculated as the 1-mo interest rate differential divided by the annualised daily volatility of spot (for G10) or 1M forwards/NDFs (for EM currencies) over the past 20 trading days, so is equivalent to an ex-ante Sharpe ratio on the currency pair. Rate differentials are based on implied yields from 1-mo FX forwards/NDFs.
- The G-10 universe comprises 15 eligible pairs: AUD, CAD, CHF, EUR, GBP, JPY, NOK, NZD and SEK vs USD; CHF, GBP, NOK and SEK vs EUR; and EUR and USD vs JPY.
- The emerging markets universe comprises 22 pairs, all versus USD:
ARS, BRL, CLP, COP, MXN, PEN, CNY, IDR, INR, KRW, MYR, PHP, SGD, THB, TWD, CZK, HUF, ILS, PLN, RUB, TRY and ZAR.
- The baskets are rebalanced monthly on the last business day of the month. Currencies in the G-10 and EM universes are ranked by carry-to-risk rather than absolute carry, and the four pairs in each universe with the highest CTR are purchased for the G-10 and EM strategies. The global carry basket also comprises four currencies – two each from the G-10 and EM universes. This restriction is imposed to control for liquidity differences between G-10 and EM currencies, since an unconstrained basket would almost always favour EM pairs for their higher carry.

2. Interest-rate momentum

- The interest-rate momentum strategy derives signals for currencies from changes in short-term interest rate expectations between two countries. The intuition is that currencies respond as much to changes in rate expectations as they do to current rate differentials (the standard carry strategy). For example, rising rates relative to the rest of the world usually signal cyclical strength which draws capital inflows and sponsors currency appreciation, even in a low-yielding currency. In previous J.P. Morgan reports, we referred to this concept as Forward Carry since changes in rate expectations could be viewed as investors' forward-looking view of FX carry.
- A simple strategy to capture this spread dynamic would be to buy the currency in whose favor rates have moved over some defined period, and to sell the currency when that rate momentum reversed. This rule would apply regardless of whether the focus currency were a high or a low-yielder, since funding currencies can rally as their yield deficit diminishes.
- The model involves three parameters: (1) the reference interest rate used to capture monetary policy expectations over the near term (we use 1-month swap rates 3 months forward); (2) the lookback period over which the change in spread is measured (we use past month, or 21 trading days); and (3) The rebalancing frequency indicating how often the change in spreads is calculated and trades executed (we use daily).

- The table on the following page provides signals for the dollar versus all major currencies (top half) and for the euro versus all major currencies (bottom half). For each bloc, the top line indicates the signal followed by the change in spread (in basis points) over the past month and performance statistics for each pair (in percent unannualised) over the past week, three months, one year and year-to-date.

3. Carry plus rate momentum

- This report combines the concepts of standard carry (model 1) and interest-rate momentum (model 2) in an attempt to better time entry into and exit from carry trades.

- The traditional approach employs so-called risk appetite measures, which are composites – and often overfitted jumbles – of volatility, credit spreads and sometimes commodity prices. J.P. Morgan's alternative focuses on more regular cyclical shifts which undermine carry trades too. That is, if currencies show an empirical tendency to rise and fall with changes in spread momentum – the conclusion from the previous interest-rate momentum model – the riskiest carry trades are those which hold high-yielders where cyclical conditions are softening, the central bank easing and interest rates falling. The safest trades would be holding the high-yielders where the economy is accelerating and/or rates rising.

- The strategy uses interest rate momentum as a simple overlay to standard carry and is employed as follows: (1) each month, rank currencies by their carry-to-risk ratio as described in the Global FX Carry Report; (2) for each currency, also measure the change in rate expectations over the past month as described in the Interest-rate Momentum Report; and (3) hold only higher-yielding currencies that also exhibit interest-rate momentum.

- Table 1 presents the daily calculations for carry-to-risk and interest-rate momentum, for investors who wish to track and position on a daily basis. To minimise transaction costs, the J.P. Morgan overlay model only rebalances once per month, when the standard carry basket rebalances. Table 2 shows current positions and returns for that monthly basket.

4. Spot momentum with rate momentum

- Spot momentum with rate momentum overlay is a variant on the typical price momentum strategies employed in all financial markets. Typical momentum frameworks involve two parameters: the momentum measure (simple price momentum, exponentially-weighted moving average) and the rebalancing frequency.

- The momentum measure can be based on simple momentum, which calculates equally-weighted performance over a previous lookback period, or an exponentially-weighted moving average, which places more emphasis on recent observations. The rebalancing frequency can be of any length – intraday, daily, weekly, monthly. For simplicity, and to fit the approach of most investment managers, we focus on daily, weekly and monthly models rather than on intra-day ones more common to algorithmic accounts.

- Previous J.P. Morgan research determined that simple spot momentum performed as well as exponentially-weighted moving averages and that medium-term momentum (1-year lookback) performed better than shorter-term model (see Alternatives to Standard Carry and Momentum in FX, Normand, August 2008).

- As a refinement on the standard spot momentum strategy which buys currencies which have outperformed recently, we add one refinement based on the interest-rate momentum model described earlier and detailed elsewhere in this chartpack of daily FX alpha models. If the interest-rate momentum model has served as useful filter for identifying carry trades which benefit from cyclical conditions as their rates rise relative to other economies, then the same concept could be used as a conditioning variable on price momentum rules. So rather than hold all currencies exhibiting positive price momentum over the medium term, this model holds those currencies which have appreciated over the past year (they exhibit positive spot momentum) and have witnessed increases in rate expectations over the past month (they exhibit interest rate momentum too).

- Table 1 outlines the pair selection process. Column # 2 and 3 identify pairs with positive spot momentum, defined as the change in the spot rate over the past 12 months. The next two columns confirm which pairs also exhibit rate momentum, defined as the change in rate spreads (1mo rates 12mos forward) over the past month. Currencies which meet both criteria are selected for inclusion in the basket. Basket returns are plotted in chart 1 and compared to those from a raw (without rate momentum filter) price momentum strategy.

5. Spot mean reversion model

- The model tests the profitability of trading mean reversion in currency markets following extraordinary spot moves in either direction. Extraordinary moves are defined as spot gains or losses of 1-sigma, 2-sigmas or 3-sigmas over the prior 5 trading days.

- If such a move has been posted based on London closing spot rates, the trading rule is to position in the opposite direction to profit from potential mean reversion. The position is held over the next 5 trading days and performance statistics such as spot return and success rate (ratio of profitable trades to total trades) calculated. Trading signals generated within that 5-day holding period are ignored for the purpose of return statistics calculations; fresh signals contribute to performance statistics only if they are generated after the 5-day holding period elapses.

- The daily report highlights those pairs which have posted 1, 2 or 3-sigma moves over the past five days. It also provides performance statistics for the contrarian trading rule over three sample periods of the past year, five years and ten years. Based on success rates and profitability, the grid characterises conviction on a high-to-low scale:

High: 70%+ success rate and 1.00% average profit.

Relatively High: 60%+ success rate and 0.5% average profit.

Medium: 51%+ success rate and 0.25% average profit.

Relatively low: 50%+ success rate and 0% average profit & below medium.

Low: all others.

6. IMM mean reversion model

- The new IMM report tracks returns from contrarian FX investing conditioned on extremes of IMM positioning. Net non-commercial positions reported weekly by CFTC are considered by many market participants to be indicative of short-term speculative investor positioning, and crowded trades to be ripe for reversal.

- For individual currencies, the backtesting rule conditions forward looking returns on ex-ante extreme thresholds of IMM positions e.g. buying EUR/USD when 1-yr z-score of positions is below -1, and selling if z-score exceeds 1.

- For the IMM-based contrarian basket, the trading rule sorts ten currencies (EUR, JPY, GBP, CHF, CAD, AUD, NZD, MXN, BRL and RUB) on 1-yr z-scores of their IMM positions every week, and buys the most oversold currency (lowest z-score) while selling the most overbought (highest z-score), subject to the restriction that z-scores in both cases satisfy the one-sigma threshold. If the latter condition is not met, over-bought/sold conditions are considered to be absent and no positions are held in the strategy basket that week.

7. J.P. Morgan short term fair value mean reversion model

- This exercise uses the mispricing from J.P. Morgan's 1-year short-term fair value models as a signal (1y z-score is used). These short-term fair value models are produced everyday in the Daily FX Fair Value Regressions Report available on jpmorganmarkets.com and model spot rates to several cyclical variables such as short-term interest rate spreads, commodity prices, VIX and sovereign spreads to determine if the pair is rich or cheap.

- Results from two strategies are presented: pair-wise approach and diversified basket approach.

- The pair-wise strategy involves buying (selling) the cross when the 1-year z-score of the residual from the short-term fair value models is 1.5 sigma or more below (above) and holding the trade till the mispricing had been reduced to 1 sigma. The table summarizes performance by trade based on a 5-year history.

- The diversified basket approach allocates risk daily to the 3 pairs that are most mispriced (basis: absolute value of 1-year z-scores) with a diversification overlay which limits exposure of each currency (but USD) to one unit. For example, if the three most mispriced pairs are dominated by GBP crosses, then only the one that is most dislocated is picked. In this case, the second and third pairs picked by the strategy will be mispriced pairs that do not involve GBP (diversification rule applies to all G10 currencies but the dollar). The

Index in chart 2 is based on the basket approach summarized separately for USD and non-USD pairs.
